

1. Automated Post-Delivery Customer Review Request

Current Manual Process: A business owner manually logs into their e-commerce platform, checks shipping statuses, notes down which packages were delivered, and manually types out emails or WhatsApp messages to each customer asking for a review.

Problem: This process is extremely time-consuming, prone to human error (forgetting to message buyers), and becomes impossible to scale as daily order volume increases.

Trigger: A webhook/API event from the courier service or e-commerce platform marking an order status as "Delivered".

Input: Customer Name, Contact Information (Email/Phone), Order ID, Product Details, and Delivery Timestamp.

Processing Required: The workflow receives the trigger, initiates a Wait/Delay node for 24 hours, formats a personalized message using the customer and product data, and routes the data to the correct communication channel.

Expected Output: A personalized review request message successfully sent via the Gmail or WhatsApp API.

Benefits of Automation: Dramatically increases review generation rates, saves the owner daily manual tracking time, and ensures consistent, timely customer engagement post-purchase.

2. Form Submission Data Extraction and Database Synchronization

Current Manual Process: An employee periodically downloads CSV files from Google Forms or Microsoft Forms and manually copies and pastes the data row-by-row into a central company database or CRM.

Problem: The process is tedious, carries a high risk of data entry typos, and creates a significant time delay between lead capture and database availability.

Trigger: A "New Form Submission" event triggered from Google Forms or Microsoft Forms.

Input: Raw JSON data payload from the submitted form containing user responses (e.g., Name, Email, Query, Service Selection).

Processing Required: Parse the incoming JSON, validate the data fields (checking for missing or incorrectly formatted inputs), map the fields to the custom database schema, and execute an SQL INSERT operation.

Expected Output: New records accurately and instantly created in the custom PostgreSQL/Supabase database.

Benefits of Automation: Eliminates manual data entry entirely, ensures zero human typos, and makes lead or survey data instantly available for downstream business operations.

3. IoT-Triggered Vending Machine Inventory Alert

Current Manual Process: Vendors visit machines on a fixed weekly schedule, regardless of actual stock levels. High-demand items often run out in one or two days, leaving empty slots until the next scheduled visit.

Problem: The business loses revenue due to out-of-stock items, and routing is inefficient (vendors visit machines that don't need refills while ignoring empty ones).

Trigger: An IoT webhook payload sent from the Raspberry Pi inside the vending machine when a specific product slot's sensor reads zero.

Input: Machine ID, Location, Empty Product Name(s), and Current Overall Stock Levels.

Processing Required: Receive the webhook, format an urgent inventory report, cross-reference the machine location to determine the responsible vendor, and compile a targeted restock notification.

Expected Output: A Telegram or SMS alert delivered immediately to the vendor detailing the exact machine location and the specific items required.

Benefits of Automation: Maximizes sales by drastically reducing out-of-stock downtime, optimizes vendor travel routes, and improves overall inventory forecasting.

4. Scheduled Multi-Platform Social Media Publishing

Current Manual Process: A small business owner sets daily alarms, manually logs into Instagram, Facebook, and Twitter, and uploads images, captions, and stories at specific times.

Problem: This disrupts the owner's daily workflow, requires them to be online at specific times regardless of other duties, and often leads to inconsistent posting.

Trigger: A Schedule node configured to fire at optimal engagement times (e.g., 10:00 AM daily).

Input: A content repository (like Google Sheets or Airtable) containing Image URLs, Captions, Hashtags, and Target Platforms.

Processing Required: The workflow fetches today's scheduled content row from the sheet, downloads the media, formats the payload for the respective social media APIs, and pushes the post.

Expected Output: Posts and stories successfully and simultaneously published across all configured social platforms via API.

Benefits of Automation: Guarantees a consistent online presence, frees up hours of the owner's time each week, and allows for bulk content creation and planning in advance.

5. AI-Driven Seasonal Inventory Forecasting & Procurement

Current Manual Process: Store managers manually review past sales spreadsheets to guess seasonal demand spikes (e.g., makeup selling out for winter weddings) and manually call suppliers to place advance bulk orders.

Problem: Relies heavily on human intuition and memory, is highly prone to stockouts if trends are missed, and analyzing large datasets manually is highly inefficient.

Trigger: A monthly or quarterly Schedule trigger initiating a historical data review cycle.

Input: Historical sales data, seasonal event calendars, current stock levels, and supplier lead times.

Processing Required: Extract historical data from the database, pass the context to an AI Agent to perform trend analysis (identifying seasonal spikes), calculate required restock quantities, and format draft purchase orders.

Expected Output: A generated procurement insight report and automated draft purchase orders sent to the manager's email for final human-in-the-loop approval.

Benefits of Automation: Prevents critical seasonal stockouts, removes human guesswork from purchasing, and leverages AI to spot hidden purchasing trends humans might overlook.
